

Multivalued Dependencies

In relation R , we say MVD $X \twoheadrightarrow Y$ holds if whenever there are tuples s and t in R such that $\pi_X(s) = \pi_X(t)$, then there is a tuple r in r such that:

1. $\pi_{XY}(r) = \pi_{XY}(s)$.
 2. $\pi_{(R-Y)\cup X}(r) = \pi_{(R-Y)\cup X}(t)$.
- I.e., r agrees with s on the attributes mentioned, and with t on X and all the attributes not mentioned.
-

Example

Consider $CTHRSG$. In addition to the FD's $C \rightarrow T$; $HR \rightarrow C$; $HT \rightarrow R$; $HS \rightarrow R$; $CS \rightarrow G$; $CH \rightarrow R$, we might reasonably expect the MVD $C \twoheadrightarrow HR$.

- That is, given a course, the hour-room pairs are independent of the teacher-student-grade triples.
 - ◆ There will be a unique teacher for the course, but student-grade information should appear in combination with each hour-room pair, since there is no logical reason to assign different grades for different hours and rooms.
-

Axiomatization of FD's + MVD's

Start with Armstrong's Axioms. Then add:

- A4: *Complementation*. If $X \twoheadrightarrow Y$ holds in R , then $X \twoheadrightarrow (R - X - Y)$.
- A5: *MVD augmentation*. If $X \twoheadrightarrow Y$, then $XZ \twoheadrightarrow YZ$ for any set of attributes Z .
- A6: *MVD transitivity*. If $X \twoheadrightarrow Y$ and $Y \twoheadrightarrow Z$, then $X \twoheadrightarrow (Z - Y)$.
- A7: *Promotion*. If $X \rightarrow Y$, then $X \twoheadrightarrow Y$.
- A8: If $X \twoheadrightarrow Y$ and $U \rightarrow V$, where:
1. U is disjoint from Y , and
 2. $V \subseteq Y$,
- then $X \rightarrow V$.
- ◆ Example: $AB \twoheadrightarrow CDE$ and $FG \rightarrow C$ imply $AB \rightarrow C$.
-

Decomposition Rules

- For FD's, we know that if $X \rightarrow A_1 \cdots A_n$, then we can “decompose” into $X \rightarrow A_1, \dots, X \rightarrow A_n$.
- MVD's do not always allow right sides of size 1.
- However, $X \twoheadrightarrow (R - X)$ always holds by A1 (trivial FD's), A7, and A4. We can break $R - X$ into *some* disjoint partition, say

$$X \twoheadrightarrow Y_1 \mid Y_2 \mid \cdots \mid Y_k$$

such that $X \twoheadrightarrow Z$ iff Z is a union of some of the Y_i 's.

Example

For *CTHRSG*, we have

$$C \twoheadrightarrow T \mid HR \mid SG$$

i.e., a course has a teacher (only one because of the FD $C \rightarrow T$), a set of hour-room pairs, and a set of student-grade pairs.

Generalized Dependencies

Unify FD's, MVD's, lossless joins, and inferences about dependencies. A *generalized dependency* consists of:

1. One or more *hypothesis* rows consisting of abstract symbols, one for each attribute of the relation in question.
 2. A *conclusion* that is either another row or an equality between two symbols.
 - ◆ If the conclusion is a row, then the GD is a *tuple-generating* dependency (TGD); if an equality it is an *equality-generating* dependency (EGD).
-

- We shall usually talk about *typed dependencies*, which means that a symbol may not appear in two different columns, and we may not equate (in the conclusion) symbols from different columns.
- Usually, we talk about *full* dependencies, meaning that the conclusion row of a TGD uses only symbols that have appeared elsewhere.

- But sometimes we like to have *partial* dependencies, where the conclusion introduces new symbols.
-

Semantics of GD's

If there is a mapping from the symbols of the hypothesis rows that turns each hypothesis into a tuple of R , then the conclusion must hold.

- If it is an EGD, then R must be such that the equated symbols are mapped to the same value.
 - If a full TGD, then the conclusion row, with the same mapping applied, must also be a row of R .
 - If a partial TGD, then there is a way to map the new symbols in the conclusion so the conclusion row becomes a tuple of R .
-

Examples

- In $R = ABCD$ the FD $AB \rightarrow C$:

A	B	C	D
a_1	b_1	c_1	d_1
a_1	b_1	c_2	d_2
			$c_1 = c_2$

- The MVD $A \twoheadrightarrow BC$:

A	B	C	D
a_1	b_1	c_1	d_1
a_1	b_2	c_2	d_2
a_1	b_1	c_1	d_2

- The *join dependency* (JD) $\bowtie(AB, BC, CD)$, which says that AB , BC , and CD are a lossless-join decomposition of $ABCD$:

A	B	C	D
a	b	c_1	d_1
a_2	b	c	d_2
a_3	b_3	c	d
a	b	c	d

The Chase Infers Full GD's

Given a set of full GD's \mathcal{G} , does another GD G follow? (I.e., does every relation instance that satisfies \mathcal{G} also satisfy G ?)

- Start with a relation R consisting of the hypothesis rows of G .
 - Repeatedly apply GD's H of \mathcal{G} to the current relation:
 - a) If H is a TGD, map its hypothesis rows to tuples of R in any way, and insert the mapped conclusion row of H into R .
 - b) If H is an EGD, map its hypothesis rows to tuples of R in any way and equate the symbols of R that H 's conclusion says are equal.
 - ◆ Remember to equate *all* occurrences of the symbols that the EGD says are equal.
 - ◆ Subtle point: if one or both of the equated symbols appear in the conclusion, change these occurrences as well; i.e., the desired conclusion must change as well as the tuples in the constructed relation.
-

- Since no new symbols are ever generated (because of the “full” assumption), eventually this process stalls.
 - At that time, if the conclusion row of G has been added to R (in the case G is a TGD) or the symbols that G says must be equal have been equated (in case G is an EGD), then conclude that G follows from \mathcal{G} . If not, then not.
-

Proof the Chase Works

- Soundness: Each inference made is sound, since it is a direct application of a given GD.
 - Completeness: Suppose the conclusion of G is not obtained. Then the final R is a counterexample:
 - ◆ It satisfies every GD in \mathcal{G} , but does not satisfy G .
-

Proof That a Key Plus Relations From a Minimal Cover Have a Lossless Join

Suppose we have a minimal cover \mathcal{F} consisting of FD's $X_i \rightarrow A_i$ for $i = 1, 2, \dots, n$, and we choose database schema

$$\{X_1 A_1, \dots, X_n A_n, K\}$$

where K is a key for the entire relation R .

- We need to infer from \mathcal{F} (written as EGD's, if you like) the JD that says the join is lossless. This JD has:
 1. A conclusion row that has “unsubscripted” symbols corresponding to each attribute.
 2. For each relation schema, a hypothesis row that has the unsubscripted symbol for an attribute if that attribute is in the schema, and a unique symbol b_j if b is the symbol for the attribute and j is the row number.
-

Example

Let $\mathcal{F} = \{A \rightarrow B, C \rightarrow D\}$. Recall the generated decomposition is $\{AB, AC, CD\}$. The JD is:

A	B	C	D
a	b	c_1	d_1
a	b_2	c	d_2
a_3	b_3	c	d
a	b	c	d

Proof That This JD Follows From the FD's

- We know $K^+ = R$.
- An induction on the order in which attributes are added to K^+ says that in the row for K , each subscripted symbol is equated to its unsubscripted version.
 - ◆ Key idea: if we use $X \rightarrow A$ to add A to K^+ , then in the row for K , all symbols for the attributes in X have lost their subscripts. Therefore, we may apply $X \rightarrow A$ to the rows for K and XA to infer that $a_j = a$, where j is the row number for XA .
- As a result, the row for K eventually loses all its subscripts, and becomes the conclusion row of the JD.
